# Confidence Intervals 

## Berlin Chen <br> Department of Computer Science \& Information Engineering <br> National Taiwan Normal University

## Introduction

- We have discussed point estimates:
- $\hat{p}$ as an estimate of a success probability, $p \quad$ (Bernoulli trials)
- $\bar{X}$ as an estimate of population mean, $\mu$
- These point estimates are almost never exactly equal to the true values they are estimating
- In order for the point estimate to be useful, it is necessary to describe just how far off from the true value it is likely to be
- Remember that one way to estimate how far our estimate is from the true value is to report an estimate of the standard deviation, or uncertainty, in the point estimate
- In this chapter, we can obtain more information about the estimation precision by computing a confidence interval when the estimate is normally distributed

## Revisit: The Central Limit Theorem

- The Central Limit Theorem
- Let $X_{1}, \ldots, X_{n}$ be a random sample from a population with mean $\mu$ and variance $\sigma^{2}$ ( $n$ is large enough)
- Let $\bar{X}=\frac{X_{1}+\cdots+X_{n}}{n}$ be the sample mean
- Let $S_{n}=X_{1}+\cdots+X_{n}$ be the sum of the sample observations. Then if $n$ is sufficiently large,
- $\bar{X} \sim N\left(\mu, \frac{\sigma^{2}}{n}\right) \quad$ sample mean is approximately normal!
- And $S_{n} \sim N\left(n \mu, n \sigma^{2}\right)$ approximately

## Example

- Assume that a large number of independent unbiased measurements, all using the same procedure, are made on the diameter of a piston. The sample mean $\bar{X}$ of the measurements is 14.0 cm (coming from a normal population due to the Central Limit Theorem ), and the uncertainty in this quantity, which is the standard deviation $\sigma_{\bar{X}}$ of the sample mean $\bar{X}$, is 0.1 cm
- So, we have a high level of confidence that the true diameter is in the interval $(13.7,14.3)$. This is because it is highly unlikely that the sample mean will differ from the true diameter by more than three standard deviations

Measured Value $=$ True Value + Bias + Random Error
random variable
constant constant random variable

## Large-Sample Confidence Interval for a Population Mean

- Recall the previous example: Since the population mean will not be exactly equal to the sample mean of 14 , it is best to construct a confidence interval around 14 that is likely to cover the population mean
- We can then quantify our level of confidence that the population mean is actually covered by the interval
- To see how to construct a confidence interval, let $\mu$ represent the unknown population mean and let $\sigma^{2}$ be the unknown population variance. Let $X_{1}, \ldots, X_{100}$ be the 100 diameters of the pistons. The observed value of $\bar{X}$ is the mean of a large sample, and the Central Limit Theorem specifies that it comes from a normal distribution with mean $\mu$ and whose standard deviation is

$$
\sigma_{\bar{X}}=\sigma / \sqrt{100}
$$

## Illustration of Capturing True Mean

- Here is a normal curve, which represents the distribution of $\bar{X}$. The middle $95 \%$ of the curve, extending a distance of $1.96 \sigma_{\bar{X}}$ on either side of the population mean $\mu$, is indicated. The following illustrates what happens if $\bar{X}$ lies within the middle $95 \%$ of the distribution:

## Illustration of Not Capturing True Mean

- If the sample mean lies outside the middle $95 \%$ of the curve: Only $5 \%$ of all the samples that could have been drawn fall into this category. For those more unusual samples the $95 \%$ confidence interval $\bar{X} \pm 1.96 \sigma_{\bar{X}}$ fails to cover the true population mean $\mu$

## Computing a 95\% Confidence Interval

- The $95 \%$ confidence interval $(\mathrm{Cl})$ is $\bar{X} \pm 1.96 \sigma_{\bar{X}}$
- So, a $95 \% \mathrm{Cl}$ for the mean is $14 \pm 1.96$ (0.1). We can use the sample standard deviation as an estimate for the population standard deviation, since the sample size is large
- We can say that we are $95 \%$ confident, or confident at the $95 \%$ level, that the population mean diameter for pistons lies, between 13.804 and 14.196
- Warning: The methods described here require that the data be a random sample from a population. When used for other samples, the results may not be meaningful

## Question?

- Does this $95 \%$ confidence interval actually cover the population mean $\mu$ ?
- It depends on whether this particular sample happened to be one whose mean (i.e. sample mean) came from the middle 95\% of the distribution or whether it was a sample whose mean (i.e. sample mean) was unusually large or small, in the outer $5 \%$ of the population
- There is no way to know for sure into which category this particular sample falls
- In the long run, if we repeated these confidence intervals over and over, then $95 \%$ of the samples will have means (i.e. sample mean) in the middle $95 \%$ of the population. Then $95 \%$ of the confidence intervals will cover the population mean

## Extension

- We are not always interested in computing 95\% confidence intervals. Sometimes, we would like to have a different level of confidence
- We can use this reasoning to compute confidence intervals with various confidence levels
- Suppose we are interested in 68\% confidence intervals, then we know that the middle $68 \%$ of the normal distribution is in an interval that extends $1.0 \sigma_{\bar{X}}$ on either side of the population mean $\mu$
- It follows that an interval of the same length around $\bar{X}$ specifically, will cover the population mean for $68 \%$ of the samples that could possibly be drawn
- For our example, a $68 \% \mathrm{Cl}$ for the diameter of pistons is $14.0 \pm$ $1.0(0.1)$, or (13.9, 14.1)

## 100(1- $\alpha$ ) \% CI

- Let $X_{1}, \ldots, X_{n}$ be a large ( $n>30$ ) random sample from a population with mean $\mu$ and standard deviation $\sigma$, so that is approximately normal. Then a level 100(1- $\alpha$ )\% confidence interval for $\mu$ is

$$
\bar{X} \pm z_{\alpha / 2} \sigma_{\bar{X}}
$$

$-z_{\alpha / 2}$ Is the $z$-score that cuts off an area of $\alpha / 2$ in the right-hand tail

- where $\sigma_{\bar{X}}=\sigma / \sqrt{n}$. When the value of $\sigma$ is unknown, it can be replaced with the sample standard deviation $s$

## Z-Table

TABLE A. 2 Cumulative normal distribution (continued)
E.g., $\bar{X} \pm z_{\alpha / 2} \sigma_{\bar{X}}$ and $\alpha=0.05$

$$
=>z_{\alpha / 2}=1.96

## Particular Cl's

- $\bar{X} \pm \frac{s}{\sqrt{n}} \quad$ is a $68 \%$ interval for $\mu$
- $\bar{X} \pm 1.645 \frac{s}{\sqrt{n}}$ is a $90 \%$ interval for $\mu$
- $\bar{X} \pm 1.96 \frac{s}{\sqrt{n}}$ is a $95 \%$ interval for $\mu$
- $\bar{X} \pm 2.58 \frac{\mathrm{~s}}{\sqrt{n}}$ is a $99 \%$ interval for $\mu$
- $\bar{X} \pm 3 \frac{s}{\sqrt{n}}$ 就 a $99.7 \%$ interval for $\mu$

Note that even for large samples, the distribution of $\bar{X}$ is only approximately normal, rather than exactly normal. Therefore, the levels stated for confidence interval are approximate.

## Example (CI Given a Level)

- Example 5.1: The sample mean and standard deviation for the fill weights of 100 boxes are $\bar{X}=12.05$ and $s=0.1$. Find an $85 \%$ confidence interval for the mean fill weight of the boxes.

Answer: To find an $85 \% \mathrm{Cl}$, set $1-\alpha=.85$, to obtain $\alpha=0.15$ and $\alpha / 2=0.075$. We then look in the table for $z_{0.075}$, the $z$-score that cuts off $7.5 \%$ of the area in the right-hand tail. We find $z_{0.075}=1.44$. We approximate $\sigma_{\bar{X}} \approx s / \sqrt{n}=0.01$.
So the $85 \% \mathrm{Cl}$ is $12.05 \pm(1.44)(0.01)$ or (12.0356, 12.0644).

## Another Example (The Level of Cl )

- Question: There is a sample of 50 micro-drills with an average lifetime (expressed as the number of holes drilled before failure) was 12.68 with a standard deviation of 6.83 . Suppose an engineer reported a confidence interval of (11.09, 14.27) but neglected to specify the level. What is the level of this confidence interval?
Answer: The confidence interval has the form $\bar{X} \pm z_{\alpha / 2} s / \sqrt{n}$. We will solve for $z_{\alpha / 2}$, and then consult the $z$ table to determine the value of $\alpha$. The upper confidence limit of 14.27 therefore satisfies the equation $14.27=12.68+$ $z_{\alpha / 2}(6.83 / \sqrt{50})$. Therefore, $z_{\alpha / 2}=1.646$. From the $z$ table, we determine that $\alpha / 2$, the area to the right of 1.646 , is approximately 0.05 . The level is $100(1-\alpha) \%$, or $90 \%$.

## More About Cl's (1/2)

- The confidence level of an interval measures the reliability of the method used to compute the interval
- A level $100(1-\alpha) \%$ confidence interval is one computed by a method that in the long run will succeed in in covering the population mean a proportion $1-\alpha$ of all the times that it is used
- In practice, there is a decision about what level of confidence to use
- This decision involves a trade-off, because intervals with greater confidence are less precise

## More About Cl's (2/2)

68\% confidence intervals $95 \%$ confidence intervals $99.7 \%$ confidence intervals

## Probability vs. Confidence

- In computing CI , such as the one of diameter of pistons: (13.804, 14.196), it is tempting to say that the probability that $\mu$ lies in this interval is $95 \%$
- The term probability refers to random events, which can come out differently when experiments are repeated
- 13.804 and 14.196 are fixed not random. The population mean is also fixed. The mean diameter is either in the interval or not
- There is no randomness involved
- So, we say that we have $95 \%$ confidence that the population mean is in this interval

## Determining Sample Size

- Back to the example of diameter of pistons: We had a Cl of (13.804, 14.196).
- This interval specifies the mean to within $\pm 0.196$. Now assume that the interval is too wide to be useful

Question: Assume that it is desirable to produce a $95 \%$ confidence interval that specifies the mean to within $\pm 0.1$

- To do this, the sample size must be increased. The width of a Cl is specified by $\pm z_{\alpha / 2} \sigma / \sqrt{n}$. If we know $\alpha$ and $\sigma$ is specified, then we can find the $n$ needed to get the desired width
- For our example, the $z_{\alpha / 2}=1.96$ and the estimated standard deviation of the population is 1 . So, $0.1=1.96(1) / \sqrt{n}$, then the $n$ accomplishes this is 385 (always round up)

## One-Sided Confidence Intervals (1/2)

- We are not always interested in Cl's with an upper and lower bound
- For example, we may want a confidence interval on battery life. We are only interested in a lower bound on the battery life. There is not an upper bound on how long a battery can last (confidence interval $=($ low bound, $\infty$ ) )
- With the same conditions as with the two-sided Cl , the level $100(1-\alpha) \%$ lower confidence bound for $\mu$ is

$$
\bar{X}-z_{\alpha} \sigma_{\bar{X}}
$$

and the level $100(1-\alpha) \%$ upper confidence bound for $\mu$ is

$$
\bar{X}+z_{\alpha} \sigma_{\bar{X}}
$$

## One-Sided Confidence Intervals (2/2)

- Example: One-sided Confidence Interval (for Low Bound)

$$
\left(\bar{X}-1.645 \sigma_{\bar{X}}, \infty\right)
$$

## Confidence Intervals for Proportions

- The method that we discussed in the last section (Sec. 5.1) was for mean from any population from which a large sample is drawn
- When the population has a Bernoulli distribution $Y$, this expression takes on a special form (the mean is equal to the success probability)
- If we denote the success probability as $p$ and the estimate for $p$ as $\hat{p}$ which can be expressed by

$$
\hat{p}=\frac{X}{n} \quad \begin{gathered}
n: \text { the sample size } \\
X \text { :number of sample items } Y_{i} \\
X=Y_{1}+Y_{2}+\cdots+Y_{n}
\end{gathered} \text { that success }
$$

- A 95\% confidence interval (CI) for $p$ is

$$
\hat{p}-1.96 \sqrt{\frac{p(1-p)}{n}}<p<\hat{p}+1.96 \sqrt{\frac{p(1-p)}{n}} .
$$

## Comments

- The limits of the confidence interval contain the unknown population proportion $p$
- We have to somehow estimate this ( $p$ )
- E.g., using $\hat{p}$
- Recent research shows that a slight modification of $n$ and an estimate of $p$ improve the interval
- Define

$$
\tilde{n}=n+4
$$

- And

$$
\tilde{p}=\frac{X+2}{\tilde{n}}
$$

## Cl for $p$

- Let $X$ be the number of successes in $n$ independent Bernoulli trials with success probability $p$ , so that $X \sim \operatorname{Bin}(n, p)$
- Then a $100(1-\alpha) \%$ confidence interval for $p$ is

$$
\widetilde{p} \pm z_{\alpha / 2} \sqrt{\frac{\widetilde{p}(1-\widetilde{p})}{\widetilde{n}}}
$$

- If the lower limit is less than 0 , replace it with 0.
- If the upper limit is greater than 1 , replace it with 1

## Small Sample CI for a Population Mean

- The methods that we have discussed for a population mean previously require that the sample size be large
- When the sample size is small, there are no general methods for finding Cl's
- If the population is approximately normal, a probability distribution called the Student's $t$ distribution can be used to compute confidence intervals for a population mean

$$
\frac{\bar{X}-\mu_{\bar{X}}}{\sigma_{\bar{X}}}=\frac{\bar{X}-\mu}{\left\langle\sigma_{1} / \sqrt{n}\right.} \neq \frac{\bar{X}-\mu}{-x^{\prime} / \sqrt{n}}
$$

## More on Cl's

- What can we do if $\bar{X}$ is the mean of a small sample?
- If the sample size is small, $s$ may not be close to $\sigma$, and $\bar{X}$ may not be approximately normal. If we know nothing about the population from which the small sample was drawn, there are no easy methods for computing Cl's
- However, if the population is approximately normal, $\bar{X}$ will be approximately normal even when the sample size $n$ is small. It turns out that we can use the quantity $(\bar{X}-\mu) /(s / \sqrt{n})$, but since $s$ may not be close to $\sigma$, this quantity instead has a Student's $t$ distribution with $n-1$ degrees of freedom, which we denote $t_{n-1}$

## Student's $t$ Distribution (1/2)

- Let $X_{1}, \ldots, X_{n}$ be a small $(n<30)$ random sample from a normal population with mean $\mu$. Then the quantity

$$
\frac{(\bar{X}-\mu)}{s / \sqrt{n}} .
$$

has a Student's $t$ distribution with $n-1$ degrees of freedom (denoted by $t_{n-1}$ ).

- When $n$ is large, the distribution of the above quantity is very close to normal, so the normal curve can be used, rather than the Student's $t$

## Student's $t$ Distribution (2/2)

- Plots of probability density function of student's $t$ curve for various of dearees

- The normal curve with mean 0 and variance 1 ( $z$ curve) is plotted for comparison
- The $t$ curves are more spread out than the normal, but the amount of extra spread out decreases as the number of degrees of freedom increases

## More on Student's $t$

- Table A. 3 called a $\boldsymbol{t}$ table, provides probabilities associated with the Student's $t$ distribution

| $\boldsymbol{l}$ | $\boldsymbol{\alpha}$ |  |  |  |  |  |  |  |  |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |

## Examples

- Question 1: A random sample of size 10 is to be drawn from a normal distribution with mean 4 . The Student's $t$ statistic $t=(\bar{X}-4) /(s / \sqrt{10})$ is to be computed. What is the probability that $t>1.833$ ?
- Answer: This $t$ statistic has $10-1=9$ degrees of freedom.

From the $t$ table, $P(t>1.833)=0.05$

- Question 2: Find the value for the $t_{14}$ distribution whose lower-tail probability is 0.01
- Answer: Look down the column headed with " 0.01 " to the row corresponding to 14 degrees of freedom. The value for $t=2.624$. This value cuts off an area, or probability, of $1 \%$ in the upper tail. The value whose lower-tail probability is $1 \%$ is -2.624

## Student's $t \mathrm{Cl}$

- Let $X_{1}, \ldots, X_{n}$ be a small random sample from a normal population with mean $\mu$. Then a level $100(1-\alpha) \% \mathrm{Cl}$ for $\mu$ is

$$
\bar{X} \pm t_{n-1, \alpha / 2} \frac{s}{\sqrt{n}} .
$$

Two-sided Cl

- To be able to use the Student's $t$ distribution for calculation and confidence intervals, you must have a sample that comes from a population that it approximately normal

## Other Student's $t$ Cl's

- Let $X_{1}, \ldots, X_{n}$ be a small random sample from a normal population with mean $\mu$
- Then a level $100(1-\alpha) \%$ upper confidence bound for $\mu \mathrm{i}$

$$
\bar{X}+t_{n-1, \alpha} \frac{s}{\sqrt{n}} . \quad \quad \text { one-sided } \mathrm{Cl}
$$

- Then a level $100(1-\alpha) \%$ lower confidence bound for $\mu$ is

$$
\bar{X}-t_{n-1, \alpha} \frac{s}{\sqrt{n}} .
$$

one-sided Cl

- Occasionally a small sample may be taken from a normal population whose standard deviation $\sigma$ is known. In these cases, we do not use the Student's $t$ curve, because we are not approximating $\sigma$ with $s$. The Cl to use here, is the one using the $z$ table, that we discussed in the first section $\frac{\bar{X}-\mu_{\bar{X}}}{\sigma_{\bar{X}}}=\frac{\bar{X}-\mu}{\sigma / \sqrt{n}}$

## Determine the Appropriateness of Using $t$ Distribution (1/2)

- We have to decide whether a population is approximately normal before using $t$ distribution to calculate Cl
- A reasonable way is construct a boxplot or dotplot of the sample
- If these plots do not reveal a strong asymmetry or any outliers, the it most cast the Student's $t$ distribution will be reliable
- Example 5.9: Is it appropriate to use $t$ distribution to calculate the Cl for a population mean given a a random sample with 15 items shown below

580, 400, 428, 825, 850,
875, 920, 550, 575, 750,
636, 360, 590, 735, 950.

## Determine the Appropriateness of Using $t$ Distribution (2/2)

- Example 5.20: Is it appropriate to use $t$ distribution to calculate the Cl for a population mean given a a random sample with 11 items shown below
$38.43,38.43,38.39,38.83,38.45$, $38.35,38.43,38.31,38.32,38.38$, 38.50 .

## CI for the Difference in Two Means (1/2)

- We also can estimate the difference between the means $\mu_{X}$ and $\mu_{Y}$ of two populations $X$ and $Y$
- We can draw two independent random samples, one from $X$ and the other one from $Y$, each of which respectively has sample means $\bar{X}$ and $\bar{Y}$
- Then construct the Cl for $\mu_{X}-\mu_{Y}$ by determining the distribution of $\bar{X}-\bar{Y}$
- Recall the probability theorem:

Let $X$ and $Y$ be independent, with $X \sim N\left(\mu_{X}, \sigma_{X}^{2}\right)$ and $Y \sim N\left(\mu_{Y}, \sigma_{Y}^{2}\right)$ Then

$$
X+Y \sim N\left(\mu_{X}+\mu_{Y}, \sigma_{X}^{2}+\sigma_{Y}^{2}\right)
$$

- And

$$
X-Y \sim N\left(\mu_{X}-\mu_{Y}, \sigma_{X}^{2}+\sigma_{Y}^{2}\right)
$$

## CI for the Difference in Two Means (2/2)

- Let $X_{1}, \ldots, X_{n_{X}}$ be a large random sample of size $n_{X}$ from a population with mean $\mu_{X}$ and standard deviation $\sigma_{X}$, and let $Y_{1}, \ldots, Y_{n_{Y}}$ be a large random sample of size $n_{Y}$ from a population with mean $\mu_{Y}$ and standard deviation $\sigma_{Y}$. If the two samples are independent, then a level $100(1-\alpha) \% \mathrm{Cl}$ for $\mu_{X}-\mu_{Y}$ is

$$
\bar{X}-\bar{Y} \pm z_{\alpha / 2} \sqrt{\frac{\sigma_{X}^{2}}{n_{X}}+\frac{\sigma_{Y}^{2}}{n_{Y}}}
$$

Two-sided Cl

$\alpha=0.05$

- When the values of $\sigma_{X}$ and $\sigma_{Y}$ are unknown, they can be replaced with the sample standard deviations $s_{X}$ and $s_{Y}$

## Cl for Difference Between Two Proportions (1/3)

- Recall that in a Bernoulli population, the mean is equal to the success probability (population proportion) $p$
- Let $X$ be the number of successes in $n_{X}$ independent Bernoulli trials with success probability $p_{X}$, and let $Y$ be the number of successes in $n_{Y}$ independent Bernoulli trials with success probability $p_{Y}$, so that $X \sim \operatorname{Bin}\left(n_{X}, p_{X}\right)$ and $Y \sim \operatorname{Bin}\left(n_{Y}, p_{Y}\right)$
- The sample proportions

$$
\begin{aligned}
& \hat{p}_{X}=\frac{X}{n_{X}} \sim N\left(p_{X}, \frac{p_{X}\left(1-p_{X}\right)}{n_{X}}\right) \quad \begin{array}{l}
\text { following from the central } \\
\text { limit theorem ( } n_{X} \text { and } n_{Y} \text { are large) } \\
\hat{p}_{Y}
\end{array}=\frac{Y}{n_{Y}} \sim N\left(p_{Y}, \frac{p_{Y}\left(1-p_{Y}\right)}{n_{Y}}\right) \\
& \Rightarrow \hat{p}_{X}-\hat{p}_{Y}=\frac{X}{n_{X}} \sim N\left(p_{X}-p_{Y}, \frac{p_{X}\left(1-p_{X}\right)}{n_{X}}+\frac{p_{Y}\left(1-p_{Y}\right)}{n_{Y}}\right)
\end{aligned}
$$

## CI for Difference Between Two Proportions (2/3)

- The difference satisfies the following inequality for $95 \%$ of all possible samples

$$
\begin{array}{cl}
\hat{p}_{X}-\hat{p}_{Y}-1.96 \sqrt{\frac{p_{X}\left(1-p_{X}\right)}{n_{X}}+\frac{p_{Y}\left(1-p_{Y}\right)}{n_{Y}}} & \\
& <p_{X}-p_{Y}<
\end{array} \text { Two-sided CI }
$$

- Traditionally in the above inequality, $p_{X}$ is replaced by $\hat{p}_{X}$ and $p_{Y}$ is replaced by $\hat{p}_{Y}$

## CI for Difference Between Two Proportions (3/3)

- Adjustment (In implementation):
- Define

$$
\tilde{n}_{X}=n_{X}+2, \tilde{n}_{Y}=n_{Y}+2, \widetilde{p}_{X}=(X+1) / \tilde{n}_{X}, \text { and } \widetilde{p}_{Y}=(Y+1) / \tilde{n}_{Y}
$$

- The $100(1-\alpha) \% \mathrm{Cl}$ for the difference $p_{X}-p_{Y}$ is

$$
\widetilde{p}_{X}-\widetilde{p}_{Y} \pm z_{\alpha / 2} \sqrt{\frac{\widetilde{p}_{X}\left(1-\widetilde{p}_{X}\right)}{n_{X}}+\frac{\widetilde{p}_{Y}\left(1-\widetilde{p}_{Y}\right)}{n_{Y}}} .
$$

- If the lower limit of the confidence interval is less than -1 , replace it with -1
- If the upper limit of the confidence interval is greater than 1 , replace it with 1

## Small-Sample CI for Difference Between Two Means (1/2)

- Let $X_{1}, \ldots, X_{n_{X}}$ be a random sample of size $n_{X}$ from a normal population with mean $\mu_{X}$ and standard deviation $\sigma_{X}$, and let $Y_{1}, \ldots, Y_{n_{Y}}$ be a random sample of size $n_{Y}$ from a normal population with mean $\mu_{Y}$ and standard deviation $\sigma_{Y}$. Assume that the two samples are independent. If the populations do not necessarily have the same variance, a level $100(1-\alpha) \% \mathrm{Cl}$ for $\mu_{X}-\mu_{Y}$ is

$$
\bar{X}-\bar{Y} \pm t_{v, \alpha / 2} \sqrt{\frac{s_{X}^{2}}{n_{X}}+\frac{s_{Y}^{2}}{n_{Y}}} . \quad \text { Two-sided Cl }
$$

- The number of degrees of freedom, $v$, is given by (rounded down to the nearest integer)

$$
v=\frac{\left(\frac{s_{X}^{2}}{n_{X}}+\frac{s_{Y}^{2}}{n_{Y}}\right)^{2}}{\frac{\left(s_{X}^{2} / n_{X}\right)^{2}}{n_{X}-1}+\frac{\left(s_{Y}^{2} / n_{Y}\right)^{2}}{n_{Y}-1}}
$$

## Small-Sample CI for Difference Between Two Means (2/2)

- If we further know the populations $X$ and $Y$ are known to have nearly the same variance. Then a $100(1-\alpha) \% \mathrm{Cl}$ for $\mu_{X}-\mu_{Y}$ is

$$
\bar{X}-\bar{Y} \pm t_{n_{X}+n_{Y}-2, \alpha / 2} s_{p} \sqrt{\frac{1}{n_{X}}+\frac{1}{n_{Y}}} . \quad \text { Two-sided Cl }
$$

- The quantity $s_{p}$ is the pooled variance, given by

$$
s_{p}^{2}=\frac{\left(n_{X}-1\right) s_{X}^{2}+\left(n_{Y}-1\right) s_{Y}^{2}}{n_{X}+n_{Y}-2}
$$

- Don't assume the population variance are equal just because the sample variance are close

## CI for Paired Data (1/3)

- The methods discussed previously for finding Cl's on the basis of two samples have required the samples are independent
- However, in some cases, it is better to design an experiment so that each item in one sample is paired with an item in the other
- Example: Tread wear of tires made of two different materials

## Cl for Paired Data (2/3)

- Let $\left(X_{1}, Y_{1}\right), \ldots,\left(X_{n}, Y_{n}\right)$ be sample pairs. Let $D_{i}=X_{i}-Y_{i}$. Let $\mu_{X}$ and $\mu_{Y}$ represent the population means for $X$ and $Y$, respectively. We wish to find a Cl for the difference $\mu_{X}-\mu_{Y}$. Let $\mu_{D}$ represent the population mean of the differences, then $\mu_{D}=\mu_{X}-\mu_{Y}$. It follows that a Cl for $\mu_{D}$ will also be a Cl for $\mu_{X}-\mu_{Y}$
- Now, the sample $D_{1}, \ldots, D_{n}$ is a random sample from a population with mean $\mu_{D}$, we can use one-sample methods to find Cls for $\mu_{D}$

## Cl for Paired Data (3/3)

- Let $D_{1}, \ldots, D_{n}$ be a small random sample ( $n<30$ ) of differences of pairs. If the population of differences is approximately normal, then a level $100(1-\alpha) \% \mathrm{Cl}$ for $\mu_{D}$ is

$$
\bar{D} \pm t_{n-1, \alpha / 2} \frac{s_{D}}{\sqrt{n}}
$$

- If the sample size is large, a level $100(1-\alpha) \% \mathrm{Cl}$ for $\mu_{D}$ is

$$
\bar{D} \pm z_{\alpha / 2} \sigma_{\bar{D}}
$$

- In practice, $\sigma_{\bar{D}}$ is approximated with $\frac{s_{D}}{\sqrt{n}}$

## Summary

- We learned about large and small Cl's for means
- We also looked at Cl's for proportions
- We discussed large and small Cl's for differences in means
- We explored Cl's for differences in proportions
